

Arkansas Game and Fish Commission Aerial Waterfowl Survey Report

January 1-5, 2023

Arkansas Game and Fish Commission staff Jason Carbaugh, Jason Jackson, Cameron Tatom and Alex Zachary conducted the annual midwinter waterfowl survey in the Mississippi Alluvial Valley (Delta), Arkansas River Valley and southwest Arkansas. Biologists conducting transect-based surveys in the Delta estimated 929,248 mallards and 1,743,324 total ducks (Table 1) and 41,017 total ducks in the Arkansas River Valley, including 25,943 mallards. Biologists performing cruise surveys in southwest Arkansas reported an estimated 14,283 ducks with 6,180 mallards (Table 2). Arctic goose population estimates totaled 1,693,343 light (lesser snow and Ross's) geese and 618,925 greater white-fronted geese in the Delta.

This year's midwinter waterfowl survey took place following an influx of Arctic air into Arkansas from across the midcontinent. A blast of Arctic air on December 22 sent temperatures below zero in parts of northern Arkansas and into the single digits in much of the state. By January 2, however, temperatures had risen sharply as major storm system approached and eventually brought massive rainfall to much of the state, particularly in the Delta. Parts of the southeast picked up more than six inches of rain. For example, the USGS gage at the Canon Brake water control structure on George H. Dunklin Jr. Bayou Meto Wildlife Management Area recorded nearly eight inches of rain and the Corning gage on the Black River recorded about four inches of rain in the early morning hours of January 3. In short, habitat conditions changed rapidly at the beginning of this survey period.

The Delta mallard population estimate was the highest during the midwinter survey since 2018 and the secondhighest since 2010 and slightly above the 2010-2023 long-term average. Total duck population estimates were well above the long-term average (Figure 1) and exceeded 1.5 million for the first time in any survey since December 2011. Mallards account for about 66 percent, on average, of all ducks in the Delta during midwinter surveys. The relatively lower 53 percent mallard estimate is a result of a notably high total duck count during this survey. Biologists estimated over 150,000 mallards in three survey zones: Bayou Meto-Lower Arkansas; Black-Upper White; and, Cache. The highest mallard and total duck estimates were in the Lower St. Francis survey zone, a region known for more boom-or-bust duck counts driven by the extent of natural flooding on the landscape. Hotspot maps indicate several duck concentration areas throughout the Delta (Figures 3 and 4).

Arkansas River Valley mallard and total duck estimates were right at long-term averages (Figure 5). The vast majority of mallards and all ducks were estimated in the Pt. Remove-Plumerville survey zone, with estimates in the Holla Bend zone a distant second like last month's surveys. Concentration maps again highlight key concentration areas in the Blackwell Bottoms (Figures 6 and 7). Southwest Arkansas cruise survey counts showed low numbers of ducks, with about half of all mallards observed along the Red River from Hwy 82 to Sulphur River.

The widespread rainfall and flooding known to boost mallard numbers in Arkansas arrived during this midwinter waterfowl survey period. Information from locations north of Arkansas suggested ducks had headed south prior to this event and no doubt found abundant new habitat to settle into across the state the first week of January, resulting in Delta mallard estimates seen only a few times over the past decade-plus. Post-season analysis of duck wings submitted by hunters will provide insight into whether improved duck production across portions of the Prairie Pothole Region in 2022 also helped bolster midcontinent mallard populations potentially bound for Arkansas and boost mallard and total duck estimates during this survey.

Table 1, continued. Waterfowl a bundance estimates in Arkansas during the late November (Nov), mid-December (Dec), early-January Midwinter Survey (MWS) and late-January (Jan) a erial waterfowl survey periods, 2009-2023, in the Mississippi Alluvial Valley (MAV) using stratified random sampling of transects.

Table 2. Waterfowl a bundance estimates in western Arkansas during the late November (Nov), mid-December (Dec), early-January Midwinter Survey (MWS) and late-January (Jan) aerial waterfowl survey periods, 2009-2023. Beginning in Jan. 2013, surveys in the Arkansas River Valley (ARV) were conducted using stratified random sampling of transects, while past ARV surveys and surveys in south west Arkansas were conducted using "cruise" surveys.

Survey Design Background

The Mississippi Alluvial Valley is an area of continental significance for migrating and wintering waterfowl, as outlined in the North American Waterfowl Management Plan, and the single most important region for wintering mallards. Habitats found in western Arkansas, including the Arkansas River Valley and southwest Arkansas, such as the Red River and Sulphur River floodplains, provide additional critical habitat for migrating and wintering waterfowl. Biologists conduct regular waterfowl surveys in these regions by aircraft up to four times each wintering period.

Winter waterfowl surveys, including the Midwinter Waterfowl Survey, have been conducted across much of the United States since 1935. Many different counting techniques have been used, and recently AGFC and partners have conducted surveys in the MAV using stratified random sampling of aerial fixed width (250m) strips, or transects, that have the advantages of extensive coverage (i.e., no area is excluded from the sample), increased accuracy by counting on fixed strips rather than traditional "cruise" surveys only counting waterfowl on large concentration areas, and availability of measures of sampling error.

Beginning in 2011 in the MAV, survey strata – or sampling zones – follow watershed boundaries (Figure 4). Watersheds in this case are simply land areas that are occupied by a drainage system consisting of a portion of a surface stream and all the tributary surface streams feeding it. For example, the Cache River strata includes lands surrounding and tributaries flowing into the Cache River from the Missouri border on the north to the Cache River's junction with the White River on the south. At the root of this sampling design is the idea that habitat within these zones will share common weather and flooding patterns and, knowing that ducks are keyed in on such patterns, duck distribution will vary among watersheds. This is not a concept foreign to those who follow ducks, particularly duck hunters, as they frequently discuss habitat and duck numbers in terms of conditions in the "Cache River bottoms," for instance. Systematically conducting aerial waterfowl surveys using this design will allow for more efficient allocation of sampling effort and provide precise estimates of waterfowl abundance in the MAV. Such a design offers an opportunity to track changes in abundance in response to changes in land use, flooding patterns or weather conditions, for example.

Before each survey period, transects to be flown are randomly selected within each strata. Biologists spend many hours in the air flying each of these transects – totaling over 3,500 miles each survey – recording all waterfowl observations using specialized computer software that collects location information in flight. Biologists also collect habitat information for each duck observation to track trends in habitat use. These data can then be used to generate population estimates for each strata and the entire MAV and develop visual representations of duck distribution (i.e., duck density maps).
